Acknowledgments

The author wishes to express his sincere appreciation to Professor Neil P. Bailey, Head of the Department of Mechanical Engineering, Rensselaer Polytechnic Institute, for the suggestion of the topic of this paper as one possible method of increasing flexibility of gas turbines and for his help and practical suggestions throughout the preparation of this paper. Also, the author appreciates the cooperation of the Commanding Officer, Naval Supply Depot, Scotia, New York, by his generous loan of the calculating machine on which the work of this paper was performed and without which, the work would have been lengthened considerably.

The author also expresses gratitude to his wife, Patty, who repeatedly stood many hours watch to prevent the baby's crying from interfering with the completion of this paper within the prescribed time limit.

The Effect of Water Injection on the Educational Gas Turbine

I. Introduction

During the course of study at Rensselaer Polytechnic Institute in the gas turbine field, one of the major limitations of gas turbine application was discussed very frequently. That limitation was the fact that the gas turbine has a very limited range of operation due to the very small margin between the gross work of the turbine and the gross work of the compressor. This margin, or net work, increases as turbine inlet temperatures increase, but the maximum temperatures at the turbine inlet are limited by available materials.

Several suggestions for increasing the net work of a gas turbine cycle have been put forth. They include increasing the machine efficiencies of the turbines and compressors by better design, increase of turbine inlet temperatures by use of better materials for burners and turbines, use of wet compression to increase the density of the working medium and to increase compressor efficiency, and the use of water injection in the combustion chamber as an effective means of lowering maximum combustor and turbine

temperatures and as a means of increasing the turbine work output without increasing the work of compression.

In January 1947, the Mechanical Engineering Department of Rensselaer Polytechnic Institute received an Educational Gas Turbine from the Aircraft Gas Turbine division of the General Electric Company at West Lynn, Massachusetts. This gas turbine is a type B22 turbo supercharger equipped with a combustion chamber, compressor inlet flow nozzle venture, compressor discharge bleed off and accessory equipment for use in the study of gas turbine performance. A complete description of the unit is contained in reference 1.

The unit, as constructed, has a very low thermal efficiency, extremely small operating range and a small output of bleed off air. Although the primary purpose of the unit is for educational purposes connected with the study of gas turbines, it is hoped that the machine can also be used to augment the supply of compressed air which is used to a considerable extent in the laboratory in which this gas turbine is installed.

Since the turbine has already been fabricated and is at present waiting being installed, it appears that the simplest method of altering it to increase the output of bleed off air is the installation of a water injection system in the combustion chamber.

The purpose of this paper is to predict the performance of the Educational Gas Turbine when such a water injection system is installed.

II. Main Text

A diagram showing the main components of the gas turbine with a water injection system, together with the reference points used in the computations is shown in Figure 10.

The compressor and turbine data used in the calculations are based on the curves of Estimated Compressor Performance and curves of Typical Turbine Efficiencies, Figure 1 and Figure 2, which were obtained from reference 1. The values of enthalpy and entropy for the various gases of combustion are obtained from Hecks Gas Tables in reference 2 and from reference 3. The values of R (gas constant) were obtained from reference 4. The values of C_p for the computation of the ratio of specific heats of the gases of combustion are obtained from figures 16 through 20. Figure 16 through figure 20 were obtained from reference 5. The C_p used in each case is obtained from the experimental curve on the graph and not from the straight line approximation of the curve. It is to be noted that the value of C_p obtained is in units of Btu per pound mole degree Fahrenheit. In order to use the values in the computations, they must be divided by the molecular weight of the gas.

All computations are based on a fuel composition of 85 per cent carbon and 15 per cent hydrogen with a lower heating value of 19100 B.t.u. per pound. Dry atmospheric air at 70°F (530°R) is assumed at the entrance of the compressor. The water injected in the combustion chamber is assumed to be in the liquid state at 70°F and to be pure so as to prevent mineral deposits from forming in the machinery. The work necessary to operate all auxiliaries such as the water pump for water injection and the blower for cooling air to the turbine has been neglected since the power source for these auxiliaries comes from an outside source rather than from the gross work of the turbine. The pressure drop through the burner and piping have been neglected making

$$\frac{P_{02}}{P_{01}} = \frac{P_{05}}{P_{06}}$$

At present, there have been no measurements of the actual pressure loss from the compressor to the turbine, so it was decided that calculations would be made on the basis that these losses are equal to zero. This assumption results in an over prediction of results, in that the net work output as calculated is higher than what can actually be expected from the unit. Experimental data on performance will thus modify the results obtained in this paper slightly. It is not expected, however, that experimental data will modify the basic conclusions drawn from this paper.

The calculation for thermal efficiency is based on the assumption that the machine using the bleed off air is 100% efficient. Any losses that occur in the use of the bleed off air should be properly charged to the machine using the air.

Calculations:

The detailed calculations for each compressor pressure ratio and each burner temperature chosen appear in the appendices. Each appendix shows the set of calculations for one pressure ratio-temperature combination using the water fuel ratio (x) as the variable. In each set of calculations the water-fuel ratio was increased from 0 to the maximum amount of water per pound of fuel that could be used and still obtain perfect combustion. Thus the maximum water fuel ratio varies from 7 with a burner temperature of $1960^{\circ} R$ to 9 when the burner temperature is $1660^{\circ} R$.

In order to determine the turbine work, it is necessary to determine C_p and k_g for each burner temperature and each combination of the gases of combustion. The calculations for enthalpy changes are made using data from Hecks Gas Tables in reference 2 and from reference 3. The calculations for C_p and k_g were made using data from figure 16 through figure 20.

In order to check the accuracy of the method of obtaining C_p and k_g using basic data from two sources, a

special calculation was made in Appendix 1 using data from Hecks Gas tables only. The comparison of the two methods shows that the value of k_g obtained using the two sources of data is smaller than the k_g which results from the use of Hecks Gas Tables exclusively. But these different values of k_g do not alter the value of the turbine work. Examination of Col. 62 and Col. 95 in Appendix 1 shows that the turbine work obtained from each method of calculation do not vary significantly. Therefore, since the calculation of C_p and k_g are considerably simpler using the data on Figure 16 through Figure 20, this method of calculation is used in all other appendices where it is necessary to evaluate k_g .

Since the value of k varies with the initial temperature of an expansion process and is practically independent of the pressure ratio of the expansion, it is necessary to evaluate k_g for each burner temperature, but once evaluated, it can be used with any pressure ratio provided the burner temperature remains constant. Values of k_g for each burner temperature are plotted on Figure 6.

III. Sample Calculation

To determine the amount of bleed off air and the thermal efficiency of the Educational Gas Turbine at point 1 on Figure 1 when the burner temperature is 1960°R . Assume a water fuel ratio of 1.0

From Figure 1 we see, that the compressor pressure ratio is 2.20, the compressor temperature rise factor is .35 and the compressor speed is 19660 R.P.M.

Lower heating value of fuel = 19100 Btu/lb.

Fuel composition is 85% carbon and 15% hydrogen.

Temperature inlet air = 530°R .

$$\text{Temperature rise factor} = .35 = \frac{T_{02} - T_{01}}{T_{01}}$$

$$\therefore T_{02} = 530^{\circ} + .35 (530) = 715.5^{\circ}\text{R}$$

Using a basic heat balance:

The heat input of the fuel minus the heat adsorbed by the products of combustion equals the heat gained by the air.

or

$$\begin{aligned} & wH - \text{weight of carbon } (h_{1960} - h_{715.5}) \\ & \quad - \text{weight of hydrogen } (h_{1960} - h_{715.5}) \\ & \quad - \text{weight of injected water } (h_{1960} - h_{715.5}) \\ & = W_a (h_{1960} - h_{715.5}) \dots \dots \dots (1) \end{aligned}$$

assume $w = 1 \text{ lb.}$

then:

$$19100 - .85 (\Delta h) - .15 (\Delta h) - x (\Delta h) = W_a (\Delta h) \dots \dots \dots (2)$$

Using the values of Δh for CO_2 , H, H_2O and air obtained from ref. 2 and ref. 3, the equation becomes

$$\begin{aligned} 19100 - .85 (374.16 - 37.60) - .15 (4978.2 - 604.6) - 1763.5x \\ = (365.0 - 42.25) W_a \dots \dots \dots (3) \end{aligned}$$

$$\text{or } 18157 - 1763.5x = (322.7) W_a \dots \dots \dots (4)$$

The first part of the paper is devoted to the study of the properties of the function $f(x)$ defined by the equation $f(x) = \sum_{n=0}^{\infty} a_n x^n$. It is shown that $f(x)$ is a continuous function of x and that it satisfies the functional equation $f(x) = x f(x^2) + 1$.

$$f(x) = \sum_{n=0}^{\infty} a_n x^n = 1 + x f(x^2)$$

$$\therefore f(x) = \frac{1}{1-x} + x f(x^2)$$

It is then shown that $f(x)$ is a rational function of x and that it can be written in the form $f(x) = \frac{P(x)}{Q(x)}$, where $P(x)$ and $Q(x)$ are polynomials with integer coefficients.

$$f(x) = \frac{1}{1-x} + x f(x^2) = \frac{1}{1-x} + x \frac{1}{1-x^2} + x^2 f(x^4) = \dots$$

$$f(x) = \frac{1}{1-x} + \frac{x}{1-x^2} + \frac{x^2}{1-x^4} + \dots = \frac{1}{1-x} \left(1 + \frac{x}{1+x} + \frac{x^2}{1+x^2} + \dots \right)$$

An equation similar to equation (4) appears at the beginning of each appendix for the determination of W_a

Now assuming that $x = 1 \frac{\text{lb. water}}{\text{lb. fuel}}$

equation (4) becomes

$$18157 - 1763.5 = (322.7) W_a \dots \dots \dots (5)$$

or $W_a = 50.80$ lbs. air per lb. fuel

In order to find the weight of O_2 , N_2 , CO_2 and H_2O in the products of combustion, it is first necessary to find the amount of O_2 required for perfect combustion of the fuel.

or $\left(\frac{32}{12} \times .85\right) + \left(\frac{16}{2} \times .15\right) =$ lbs of O_2 required for

perfect combustion $\dots \dots \dots (6)$

or $2.266 + 1.200 = 3.466$ lbs O_2 required $\dots \dots \dots (7)$

The amount of O_2 required for perfect combustion remains constant in all calculations and appears as a constant in the appendices.

The composition of air by weight is about 23% O_2 and 77% N_2 , therefore the total O_2 available is $50.80 \times .23 = 11.68$ lbs. $O_2 \dots \dots \dots (8)$

The amount of free O_2 in the products of combustion equals the O_2 available minus the O_2 required for combustion of the fuel, or

$$11.68 - 3.466 = 8.21 \text{ lbs. free } O_2 \dots \dots \dots (9)$$

The Committee wishes to express its appreciation to the members of the Board of Directors for their cooperation and assistance in the preparation of this report.

The Committee has the honor to acknowledge the assistance of the following persons:

Mr. J. H. Smith, Secretary

Mr. J. H. Smith, Secretary

Mr. J. H. Smith, Secretary

The Committee has the honor to acknowledge the assistance of the following persons:

Mr. J. H. Smith, Secretary

Mr. J. H. Smith, Secretary

Mr. J. H. Smith, Secretary

Mr. J. H. Smith, Secretary

Mr. J. H. Smith, Secretary

Mr. J. H. Smith, Secretary

Mr. J. H. Smith, Secretary

Mr. J. H. Smith, Secretary

Mr. J. H. Smith, Secretary

Mr. J. H. Smith, Secretary

Mr. J. H. Smith, Secretary

Mr. J. H. Smith, Secretary

$$\text{The amount of } N_2 = (50.80)(.77) = 39.12 \text{ lbs.} \dots (10)$$

$$\text{The amount of } CO_2 = \frac{44}{12} (.85) = 3.116 \text{ lbs.} \dots (11)$$

$$\text{The amount of } H_2O = \frac{18}{2} (.15) + x = 1.35 + 1 = 2.35 \text{ lbs.} (12)$$

The amount of CO_2 and H_2O formed by the combustion of the fuel remain constant for all calculations and appear as constants in the appendices.

The addition of the weights of O_2 , N_2 , CO_2 and H_2O in the combustion products gives the total weight of the combustion gases. The total weight of the combustion gases is also equal to the weight of fuel (always assumed to be 1 lb.) plus the water-fuel ratio plus the weight of air.

For this case

$$\begin{aligned} \text{Weight of combustion products} &= 8.21 + 39.12 + 3.116 + 2.35 \\ &= 52.80 \text{ lbs.} \dots (13) \end{aligned}$$

Now proceed to find a weighted R_g for the combustion gases taking into account the actual composition of the gas mixture.

From ref. 4

$$R_{O_2} = 48.31$$

$$R_{N_2} = 55.16$$

$$R_{CO_2} = 35.13$$

$$R_{H_2O} = 35.81$$

$$R_g = \frac{w_{O_2}(R_{O_2}) + w_{N_2}(R_{N_2}) + w_{CO_2}(R_{CO_2}) + w_{H_2O}(R_{H_2O})}{w_{O_2} + w_{N_2} + w_{CO_2} + w_{H_2O}} \dots (14)$$

Let $x = a + b\sqrt{2} + c\sqrt{3} + d\sqrt{6}$ be an element of $\mathbb{Q}(\sqrt{2}, \sqrt{3})$.

Then $x + \bar{x} = 2a$ and $x - \bar{x} = 2b\sqrt{2} + 2c\sqrt{3} + 2d\sqrt{6}$.

Thus $a = \frac{x + \bar{x}}{2}$ and $b\sqrt{2} + c\sqrt{3} + d\sqrt{6} = \frac{x - \bar{x}}{2}$.

Now, if x is rational, then $\bar{x} = x$ and $b = c = d = 0$.
If x is not rational, then $\bar{x} \neq x$ and b, c, d are not all zero.
Hence, x is not rational.

The addition of \bar{x} to x gives $2a$.

Let $y = e + f\sqrt{2} + g\sqrt{3} + h\sqrt{6}$ be another element of $\mathbb{Q}(\sqrt{2}, \sqrt{3})$.

Then $y + \bar{y} = 2e$ and $y - \bar{y} = 2f\sqrt{2} + 2g\sqrt{3} + 2h\sqrt{6}$.

Adding $x + y$ and $\bar{x} + \bar{y}$ gives $2(a + e)$.

Adding $x - y$ and $\bar{x} - \bar{y}$ gives $2(b - f)\sqrt{2} + 2(c - g)\sqrt{3} + 2(d - h)\sqrt{6}$.

Thus

$x + y = 2(a + e) + 2(b - f)\sqrt{2} + 2(c - g)\sqrt{3} + 2(d - h)\sqrt{6}$.

Let $z = i + j\sqrt{2} + k\sqrt{3} + l\sqrt{6}$ be a third element of $\mathbb{Q}(\sqrt{2}, \sqrt{3})$.

Then $z + \bar{z} = 2i$ and $z - \bar{z} = 2j\sqrt{2} + 2k\sqrt{3} + 2l\sqrt{6}$.

Adding $x + y + z$ and $\bar{x} + \bar{y} + \bar{z}$ gives $2(a + e + i)$.

Adding $x - y - z$ and $\bar{x} - \bar{y} - \bar{z}$ gives $2(b - f - j)\sqrt{2} + 2(c - g - k)\sqrt{3} + 2(d - h - l)\sqrt{6}$.

Thus

$$2(a + e + i) = (x + y + z) + (\bar{x} + \bar{y} + \bar{z})$$

$$2(b - f - j)\sqrt{2} + 2(c - g - k)\sqrt{3} + 2(d - h - l)\sqrt{6} = (x - y - z) + (\bar{x} - \bar{y} - \bar{z})$$

$$2(b - f - j)\sqrt{2} + 2(c - g - k)\sqrt{3} + 2(d - h - l)\sqrt{6} = (x - y - z) + (\bar{x} - \bar{y} - \bar{z})$$

$$2(b - f - j)\sqrt{2} + 2(c - g - k)\sqrt{3} + 2(d - h - l)\sqrt{6} = (x - y - z) + (\bar{x} - \bar{y} - \bar{z})$$

$$(x + y + z) + (\bar{x} + \bar{y} + \bar{z}) = 2(a + e + i) + \frac{(x - y - z) + (\bar{x} - \bar{y} - \bar{z})}{\sqrt{2} + \sqrt{3} + \sqrt{6}}$$

O ₂	8.21 (48.31)	=	396.6
N ₂	39.12 (55.16)	=	2157.9
CO ₂	3.116 (35.13)	=	109.6
H ₂ O	2.35 (85.81)	=	<u>201.6</u>
Total		=	2865.7

$$\text{and } R_g = \frac{2865.7}{52.80} = 54.27$$

Now find the weighted C_p for the combustion gases taking into account the actual composition of the gas mixture.

From figures 16 through 20, at 1960° R

C_{pO_2}	=	.2641 Btu/lb.
C_{pN_2}	=	.2829 Btu/lb.
C_{pCO_2}	=	.3002 Btu/lb.
C_{pH_2O}	=	.5622 Btu/lb.

and similar to equation (14)

$$C_p = \frac{W_{O_2}(C_{pO_2}) + W_{N_2}(C_{pN_2}) + W_{CO_2}(C_{pCO_2}) + W_{H_2O}(C_{pH_2O})}{W_{O_2} + W_{N_2} + W_{CO_2} + W_{H_2O}} \quad \dots (15)$$

O ₂	8.21 (.2641)	=	2.1683
N ₂	39.12 (.2829)	=	11.0631
CO ₂	3.116 (.3002)	=	.9354
H ₂ O	2.35 (.5622)	=	<u>1.3212</u>
Total		=	15.4880

$$\text{and } C_p = \frac{15.4880}{52.80} = .2933$$

Now find k_g for the combustion gases

$$C_p = \left(\frac{k}{k-1} \right) \frac{R}{J} \dots \dots \dots (16)$$

$$\text{or } k = \frac{\frac{J}{R} C_p}{\frac{J}{R} C_p - 1} \dots \dots \dots (17)$$

Using the values of R_g and C_p found above

$$k_g = \frac{\frac{778 (.2933)}{54.27}}{\frac{778 (.2933)}{54.27} - 1} = \frac{4.206}{3.206} = 1.312$$

In order to enter figure 2 to obtain a turbine efficiency, it is first necessary to obtain the ratio W/v_n

By measurement, the average turbine blade radius is 5.62 inches or .468 feet. To convert the blade speed in RPM to ft/sec. use the formula:

$$W = 2\pi r \times \frac{\text{R.P.M.}}{60} \dots \dots \dots (18)$$

$$\text{in this case } W = 2\pi R \left(\frac{19660}{60} \right) = 963 \text{ ft/sec.}$$

Columns 54 and 55 in Appendix 1 show the conversion of turbine blade speed in R.P.M. to feet per second and the results are plotted on figure 3 so that the conversion may be picked off the graph.

From page 5, chapter 1 of reference 6

$$\frac{v_n}{\sqrt{k_g R T_o}} = \frac{M}{\sqrt{1 + \frac{k-1}{2} M^2}} \dots \dots \dots (19)$$

$$\text{or } v_n = M \sqrt{\frac{k_g R_g T_o}{1 + \frac{k_g - 1}{2} M^2}} \dots \dots \dots (20)$$

$$(10) \quad \frac{1}{2} \left(\frac{1}{2} + \frac{1}{2} \right) = \frac{1}{2}$$

$$\frac{1}{2}$$

$$(11) \quad \frac{1}{2} \left(\frac{1}{2} + \frac{1}{2} \right) = \frac{1}{2}$$

Let us now consider the case of a general function $f(x)$.

$$f(x) = \frac{1}{2} \left(\frac{1}{2} + \frac{1}{2} \right) = \frac{1}{2}$$

It is clear that the function $f(x)$ is not a constant function.

It is also clear that the function $f(x)$ is not a linear function.

It is also clear that the function $f(x)$ is not a quadratic function.

It is also clear that the function $f(x)$ is not a cubic function.

It is also clear that the function $f(x)$ is not a quartic function.

It is also clear that the function $f(x)$ is not a quintic function.

It is also clear that the function $f(x)$ is not a sextic function.

It is also clear that the function $f(x)$ is not a septic function.

It is also clear that the function $f(x)$ is not an octic function.

It is also clear that the function $f(x)$ is not a nonic function.

It is also clear that the function $f(x)$ is not a decic function.

It is also clear that the function $f(x)$ is not an undecimic function.

It is also clear that the function $f(x)$ is not a duodecimic function.

It is also clear that the function $f(x)$ is not a tridecimic function.

It is also clear that the function $f(x)$ is not a quattuordecimic function.

It is also clear that the function $f(x)$ is not a quindecimic function.

It is also clear that the function $f(x)$ is not a sexdecimic function.

It is also clear that the function $f(x)$ is not a septemdecimic function.

It is also clear that the function $f(x)$ is not an octodecimic function.

It is also clear that the function $f(x)$ is not a novemdecimic function.

It is also clear that the function $f(x)$ is not a vigintimic function.

It is also clear that the function $f(x)$ is not a unguicquagintimic function.

It is also clear that the function $f(x)$ is not a duogingentimic function.

To determine the critical pressure ratio of the turbine nozzle, use the equation relating Mach. Number with pressure ratio from page 6, chapter 1 of reference 6.

$$\frac{P_0}{P} = \left[\frac{k-1}{2} \left(M^2 + \frac{2}{k-1} \right) \right]^{\frac{k}{k-1}} \dots \dots \dots (21)$$

Substituting $M = 1.0$ and the value of k obtained above ($k = 1.312$) and solving equation (21), the critical pressure ratio is found

$$\frac{P_0}{P} = 1.83$$

Since $\frac{P_{05}}{P_{06}} = 2.20$ is greater than the critical pressure ratio, we may use $M = 1.0$ in equation 20. Equation 20 then becomes

$$v_n = \sqrt{\frac{k_g R_g (32.17)(1960)}{1 + \frac{k_g - 1}{2}}} = \sqrt{\frac{k_g R_g 63053}{1 + \frac{k_g - 1}{2}}} \dots \dots (22)$$

An equation similar to equation (22) appears at the beginning of each appendix for the determination of v_n .

Using the values of k_g and R_g as previously determined and substituting them in equation (22),

$$v_n = \frac{4,489,500}{1.156} = 1971 \text{ ft/sec.}$$

therefore

$$\frac{W}{v_n} = \frac{963}{1971} = .488 \dots \dots \dots (23)$$

be shown assuming the validity of the following:

Let $f(x)$ be a function of x and let $f'(x)$ be its derivative.

Then the derivative of $f(x)$ is given by

the following:

$$f'(x) = \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} = \lim_{h \rightarrow 0} \left[\frac{f(x+h) - f(x)}{h} \right] = \frac{f'(x)}{1}$$

where $f'(x)$ is the derivative of $f(x)$ at the point x .

where $f'(x)$ is the derivative of $f(x)$ at the point x .

where $f'(x)$ is the derivative of $f(x)$ at the point x .

$$f'(x) = \frac{f(x+h) - f(x)}{h}$$

where $f'(x)$ is the derivative of $f(x)$ at the point x .

where $f'(x)$ is the derivative of $f(x)$ at the point x .

where $f'(x)$ is the derivative of $f(x)$ at the point x .

$$f'(x) = \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} = \lim_{h \rightarrow 0} \left[\frac{f(x+h) - f(x)}{h} \right] = \frac{f'(x)}{1}$$

where $f'(x)$ is the derivative of $f(x)$ at the point x .

where $f'(x)$ is the derivative of $f(x)$ at the point x .

where $f'(x)$ is the derivative of $f(x)$ at the point x .

where $f'(x)$ is the derivative of $f(x)$ at the point x .

$$f'(x) = \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} = \lim_{h \rightarrow 0} \left[\frac{f(x+h) - f(x)}{h} \right] = \frac{f'(x)}{1}$$

where $f'(x)$ is the derivative of $f(x)$ at the point x .

$$f'(x) = \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h} = \lim_{h \rightarrow 0} \left[\frac{f(x+h) - f(x)}{h} \right] = \frac{f'(x)}{1}$$

Entering figure 2 with the arguments $\frac{P_{05}}{P_{06}} = 2.20$ and

$\frac{W}{V_n} = .483$, the turbine efficiency is determined to be 63.3%

To determine the ideal temperature of the combustion gases leaving the turbine, use the equation for reversible expansion

$$\frac{T_{05}}{T_{0'6}} = \left(\frac{P_{05}}{P_{06}} \right)^{\frac{k-1}{k}} \dots \dots \dots (24)$$

Using $\frac{P_{05}}{P_{06}} = 2.20$, $T_{05} = 1960^\circ R$ and $k = 1.312$ in equation (24)

$$T_{0'6} = 1625^\circ R.$$

$$\text{By definition } \eta_T = \frac{T_{05} - T_{06}}{T_{05} - T_{0'6}} \dots \dots \dots (25)$$

$$\text{or } \Delta T_0 = \eta_T (\Delta T_{0'}) \dots \dots \dots (26)$$

$$\text{Using } \eta_T = 63.3, \Delta T_{0'} = 1960 - 1625$$

$$\Delta T_0 = 63.3 (335) = 212^\circ$$

From the general energy equation

$$dL = C_p dT \dots \dots \dots (27)$$

or

$$L_T = \int_{T_{06}}^{T_{05}} C_p dT = C_p \Delta T_0 \dots \dots \dots (28)$$

$$\text{Using } C_p = .2933 \text{ and } \Delta T_0 = 212$$

$$L_T = .2933 (212) = 62.2 \text{ Btu/lb combustion gas}$$

The ratio of lbs. of combustion gas to lbs. of inlet or compressor air is $\frac{52.80}{50.80} = 1.040$

where Δ is the difference between the two values of Δ and Δ is the difference between the two values of Δ .

where Δ is the difference between the two values of Δ and Δ is the difference between the two values of Δ .

where Δ is the difference between the two values of Δ and Δ is the difference between the two values of Δ .

$$\Delta = \frac{1}{2} \left(\frac{\Delta}{\Delta} \right) = \frac{\Delta}{2}$$

where Δ is the difference between the two values of Δ and Δ is the difference between the two values of Δ .

$$\Delta = \frac{1}{2} \left(\frac{\Delta}{\Delta} \right) = \frac{\Delta}{2}$$

$$\Delta = \frac{1}{2} \left(\frac{\Delta}{\Delta} \right) = \frac{\Delta}{2}$$

$$\Delta = \frac{1}{2} \left(\frac{\Delta}{\Delta} \right) = \frac{\Delta}{2}$$

$$\Delta = \frac{1}{2} \left(\frac{\Delta}{\Delta} \right) = \frac{\Delta}{2}$$

$$\Delta = \frac{1}{2} \left(\frac{\Delta}{\Delta} \right) = \frac{\Delta}{2}$$

where Δ is the difference between the two values of Δ and Δ is the difference between the two values of Δ .

$$\Delta = \frac{1}{2} \left(\frac{\Delta}{\Delta} \right) = \frac{\Delta}{2}$$

$$\Delta = \frac{1}{2} \left(\frac{\Delta}{\Delta} \right) = \frac{\Delta}{2}$$

$$\Delta = \frac{1}{2} \left(\frac{\Delta}{\Delta} \right) = \frac{\Delta}{2}$$

$$\Delta = \frac{1}{2} \left(\frac{\Delta}{\Delta} \right) = \frac{\Delta}{2}$$

where Δ is the difference between the two values of Δ and Δ is the difference between the two values of Δ .

$$\Delta = \frac{1}{2} \left(\frac{\Delta}{\Delta} \right) = \frac{\Delta}{2}$$

Multiplying the turbine work by the ratio of combustion products to inlet air gives

$$L_T = 62.2 (1.040) = 64.7 \text{ Btu/lb. inlet air}$$

From equation (27), the compression work equals

$$L_C = \int_{T_{01}}^{T_{02}} C_p dT \dots \dots \dots (29)$$

In this example

$$L_C = h_{715.5} - h_{530} = 44.6 \text{ Btu/lb.}$$

The net work of the gas turbine cycle is

$$W_b L_n = [L_T(W_a - W_b) - L_C(W_a)] W_b \dots \dots \dots (30)$$

An overall work balance gives

$$(W_a) L_C + W_b L_n = (W_a - W_b) L_T \dots \dots \dots (31)$$

Combining equation (31) with equation (30)

$$L_C(W_a) + [L_T(W_a - W_b) - L_C(W_a)] W_b = L_T(W_a - W_b) \dots (32)$$

Assume $W_a = 1 \text{ lb./sec.}$ then

$$L_C + [L_T(1 - W_b) - L_C] W_b = L_T(1 - W_b) \dots \dots \dots (33)$$

or using $L_C = 44.6 \text{ Btu/lb.}$

$$44.6 + [L_T(1 - W_b) - 44.6] W_b = L_T(1 - W_b) \dots \dots \dots (34)$$

or simplifying

$$L_T(W_b)^2 + [44.60 - 2L_T] W_b + L_T - 44.60 = 0 \dots \dots \dots (35)$$

At the beginning of each appendix there appears a formula similar to equation (35) for the determination of W_b .

$$x_1^2 + x_2^2 + \dots + x_n^2 = 1 \quad (1)$$

Let x_1, x_2, \dots, x_n be real numbers satisfying (1). Then

$$x_1^2 + x_2^2 + \dots + x_n^2 = 1 \quad (2)$$

is a necessary condition for the existence of a solution to (1).

$$x_1^2 + x_2^2 + \dots + x_n^2 = 1 \quad (3)$$

is a sufficient condition for the existence of a solution to (1).

$$x_1^2 + x_2^2 + \dots + x_n^2 = 1 \quad (4)$$

is a necessary and sufficient condition for the existence of a solution to (1).

$$x_1^2 + x_2^2 + \dots + x_n^2 = 1 \quad (5)$$

is a necessary and sufficient condition for the existence of a solution to (1).

$$x_1^2 + x_2^2 + \dots + x_n^2 = 1 \quad (6)$$

is a necessary and sufficient condition for the existence of a solution to (1).

$$x_1^2 + x_2^2 + \dots + x_n^2 = 1 \quad (7)$$

is a necessary and sufficient condition for the existence of a solution to (1).

$$x_1^2 + x_2^2 + \dots + x_n^2 = 1 \quad (8)$$

is a necessary and sufficient condition for the existence of a solution to (1).

is a necessary and sufficient condition for the existence of a solution to (1).

is a necessary and sufficient condition for the existence of a solution to (1).

Equation (35) is a quadratic equation in w_b .

To solve it, use the regular quadratic solution

$$w_b = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} \dots \dots \dots (36)$$

$$\text{let } a = L_T$$

$$\text{let } b = L_C - 2L_T$$

$$\text{let } c = L_T - L_C$$

For this example

$$a = 64.7 \quad b = -84.6 \quad \text{and } c = 20.0$$

Placing these values in equation 36

$$w_b = \frac{84.6 \pm 44.6}{129.2}$$

Using the plus sign we obtain the impossible answer

that $w_b = 1 \text{ lb. air/lb. inlet air}$

Using the negative sign

$w_b = .309 \text{ lbs. air/lb. inlet or compressor air. } \underline{\text{Answer.}}$

$$\text{Thermal efficiency} = \frac{\text{net heat output}}{\text{net heat input}} \times 100$$

$$\text{or } n = \frac{w_b \times w_a \times L_C \times 100}{19100} \dots \dots \dots (37)$$

Using $w_a = 50.80 \text{ lbs. air/lb. fuel}$, $w_b = .309 \text{ lbs. air/lb.}$

inlet air, $L_C = 44.60$

$$n = \frac{.309 (50.80) (44.60) 100}{19100} = 3.67\% \underline{\text{Answer}}$$

An equation similar to equation (37) appears at the

beginning of each appendix for the determination of n .

6082

The value of λ is determined by the condition
 that the function $\psi(x)$ must be continuous at $x=0$.
 This gives the equation

$$\begin{aligned}
 \psi(0^+) &= \psi(0^-) \\
 \frac{1}{\sqrt{2\pi}} \int_0^\infty \cos(kx) dx &= \frac{1}{\sqrt{2\pi}} \int_0^\infty \cos(kx) dx
 \end{aligned}$$

For this equation to hold, the function $\psi(x)$ must be continuous at $x=0$.
 This gives the equation

$$\begin{aligned}
 \psi(0^+) &= \psi(0^-) \\
 \frac{1}{\sqrt{2\pi}} \int_0^\infty \cos(kx) dx &= \frac{1}{\sqrt{2\pi}} \int_0^\infty \cos(kx) dx
 \end{aligned}$$

The value of λ is determined by the condition
 that the function $\psi(x)$ must be continuous at $x=0$.
 This gives the equation

$$\begin{aligned}
 \psi(0^+) &= \psi(0^-) \\
 \frac{1}{\sqrt{2\pi}} \int_0^\infty \cos(kx) dx &= \frac{1}{\sqrt{2\pi}} \int_0^\infty \cos(kx) dx
 \end{aligned}$$

The value of λ is determined by the condition
 that the function $\psi(x)$ must be continuous at $x=0$.
 This gives the equation

2662

All work in the appendices is similar to that in the sample calculation above except that in the first part of Appendix 1, as mentioned before, the values of k_g and C_p are calculated from Hecks Gas Tables. The method used in this calculation is outlined in the notes at the beginning of the appendix. Another exception is that in Appendix B the pressure ratio $\frac{P_{05}}{P_{06}}$ is less than

the critical pressure ratio for the combustion gases through the turbine nozzle and M can not be assumed equal to 1 as in the sample calculation. The method of procedure in this case is outlined in the notes at the beginning of Appendix B.

IV. Results of Calculations

Calculations were made for the following combinations of $\frac{P_{05}}{P_{06}}$ and T_{05} for points 1, 2, and 3 on figure 1:

$\frac{P_{05}}{P_{06}}$	T_{05}	
2.20	1960°R	- Appendix 1
2.00	1960°R	- Appendix A
1.80	1960°R	- Appendix B
2.20	1860°R	- Appendix C
2.20	1760°R	- Appendix D
2.20	1660°R	- Appendix E

Figure 5 shows the comparison of the net output (W_p) when burner temperature T_{05} is kept constant at 1960°R and the pressure ratio is varied from 1.80 to 2.20. It is well to note at this point that pressure ratio can be varied by changing the speed of the gas turbine by varying the amount of bleed off air and the amount of fuel injected. From Figure 5, the amount of bleed off air increases as the water fuel ratio increases. With a water fuel ratio of 7, the output increases approximately 100% over that obtained without the use of water injection.

Figure 7 shows the net output when the pressure ratio is kept constant at 2.20 and the burner outlet temperature is varied from 1960°R to 1660°R . This graph shows that at lower temperatures where more water may be injected and still keep perfect combustion of fuel the output of the gas turbine is increased as much as 370%. This graph also shows that by the use of the correct water fuel ratio the output at low burner temperatures can be increased above that obtained by the use of high temperatures alone without water injection.

A comparison of Figures 5 and 7 shows that for any given water fuel ratio, the net output of the cycle can be varied over a wider range by varying the burner temperature than by varying the pressure ratio. From this fact, we see that the turbine is much more sensitive to temperature changes than it is to pressure changes.

Figure 8 shows the cycle or thermal efficiencies attained at a pressure ratio of 2.20 for various burner temperatures. Due to the losses incurred by the latent heat of vaporization of water, it is expected that overall efficiency will drop with increasing amounts of water. This is generally the case, but since the turbine efficiency of this gas turbine is so low (in the vicinity of 62%) that overall efficiency actually increases with water injection at low burner temperatures. From the graph we see that the maximum efficiency with a burner temperature of 1660°R occurs in the vicinity of a water fuel ratio of 6.0. Beyond the water fuel ratio of 6.0, the thermal efficiency at 1660°R actually exceeds that obtained with a burner temperature of 1960°R . Indeed, this graph indicates that by use of water injection the gas turbine could be made to operate at temperatures so low that it wouldn't even idle without the use of water. In order to do this it would be necessary to initially use a high burner temperature, inject a large amount of water, and then gradually reduce temperature to the low temperature desired.

Figure 9 shows the thermal efficiencies for a constant burner temperature and pressure ratios from 1.80 to 2.20. As expected for the high burner temperature, the efficiency decreases steadily as the water fuel ratio is increased. As the pressure ratio is increased, for any water fuel ratio, the thermal efficiency is increased.

V. Recommendations and Conclusion

The above results show that the installation of water injection on the combustion chamber of the Educational Gas Turbine would result in a substantial increase in the output of compressed air from the unit and furthermore that the water injection will increase the overall efficiency of the plant at high pressure ratios and low burner temperatures. It is recommended that this alteration be made.

Obviously, from figure 1, calculations could be made for a great number of combinations of pressure ratio and burner temperatures that were not made in this paper. The author picked the points calculated with the following limitations in mind: The maximum operating speed of the gas turbine is about 21,000 R.P.M., the maximum allowable burner temperature is 1960°R , and the operating range will have to be on the flat portions of the pressure ratio volume flow curves and the compressor efficiency curves. It is recommended that any future calculations made on this turbine be made at lower pressure ratios than those chosen by the author.

The first thing I saw when I stepped out

of the house was the beautiful view of the

mountains. The house was built on a hillside

and the view was just what I needed. The

house was built in the style of a

small cottage and it was just what I

needed. It was just what I needed.

It was just what I needed.

It was just what I needed.

It was just what I needed.

It was just what I needed.

It was just what I needed.

It was just what I needed.

It was just what I needed.

It was just what I needed.

It was just what I needed.

It was just what I needed.

It was just what I needed.

It was just what I needed.

It was just what I needed.

It was just what I needed.

Appendix I

Tables of calculations assuming a compressor pressure ratio of 2.20 and a burner temperature of 1960°R at point 1 on figure 1. 19660 R.P.M. = 963 ft/sec.

From Fig. 1, compressor temperature rise factor = .35

$$T_{02} = 530 + .35 (530) = 715.5^{\circ}\text{R}$$

Using Hecks Gas Tables

$$19100 - .85 (374.16 - .37.60) - .15(4978.2 - 604.6)$$

$$- 1763.5x - W_a(365.0 - 42.25)$$

$$\text{or } 18157 - (1763.5)x - W_a(322.7)$$

Columns 1 through 4 are calculated from the above equation.

Columns 5 through 9 give the amounts of O₂, N₂, CO₂ and H₂O in the products of combustion. Column 10 gives the total pounds of combustion products per pound of fuel.

Columns 11 through 16 show the calculation of S_p for the products of combustion at 1960°R from information in Hecks Gas Tables. Columns 17 through 22 show the calculation of R_g for the gases of combustion. Columns 23 through 34 show the construction of tables of S_p for products of combustion at 1600°R and 1700°R.

$$\Delta S_T = \frac{R_g}{J} \ln \frac{P_{03}}{P_{06}}$$

$$\Delta S_T = \frac{R_g}{778} \ln 2.20 = R_g(.0010132)$$

$$S_{p6} = S_{p5} - \Delta S_T$$

Let us consider the following example:

Let $f(x) = x^2 + 1$ and $g(x) = x^2 - 1$.

Then $f(x)g(x) = (x^2 + 1)(x^2 - 1) = x^4 - 1$.

Now let $h(x) = x^4 - 1$.

$$h(x) = x^4 - 1$$

$$h(x) = (x^2 + 1)(x^2 - 1)$$

Using the identity

$$x^4 - 1 = (x^2 + 1)(x^2 - 1)$$

$$x^4 - 1 = (x^2 + 1)(x^2 - 1)$$

$$x^4 - 1 = (x^2 + 1)(x^2 - 1)$$

Column 1 shows a new relation between the two functions.

Column 2 shows a new relation between the two functions.

Column 3 shows a new relation between the two functions.

Let us now consider the following example:

Let $f(x) = x^2 + 1$ and $g(x) = x^2 - 1$.

Then $f(x)g(x) = (x^2 + 1)(x^2 - 1) = x^4 - 1$.

Now let $h(x) = x^4 - 1$.

Using the identity

$$x^4 - 1 = (x^2 + 1)(x^2 - 1)$$

$$x^4 - 1 = (x^2 + 1)(x^2 - 1)$$

$$\frac{x^4 - 1}{x^2 - 1} = x^2 + 1$$

$$\frac{x^4 - 1}{x^2 - 1} = x^2 + 1$$

$$x^2 + 1 = \frac{x^4 - 1}{x^2 - 1}$$

Column 35 gives the calculation for ΔS_T

Column 36 gives the calculation for S_{p6}

Columns 37 through 40 show the calculation for T_{o6}'

$$\frac{T_{o5}}{T_{o6}'} = \left(\frac{P_{o5}}{P_{o6}} \right)^{\frac{k-1}{k}}$$

$$\text{or } k = \frac{1}{\frac{\ln \frac{T_{o5}}{T_{o6}'}}{1 - \frac{\ln \frac{P_{o5}}{P_{o6}}}{k}}}$$

Columns 41 through 45 show the calculation for k_g

$$C_{pg} = \frac{k}{k-1} \frac{R}{J}$$

Columns 46 through 48 show the calculation for C_p

$$\frac{v_n}{\sqrt{k g R T_o}} = \frac{M}{\sqrt{1 + \frac{k-1}{2} M^2}}, \quad M = 1.0 \text{ at nozzle throat}$$

$$\text{then } v_n = \sqrt{\frac{k R (32.17) 1960}{1 + \frac{k-1}{2}}} = \sqrt{\frac{k R_6 63053}{1 + \frac{k-1}{2}}}$$

Columns 49 through 53 show the calculation for v_n

Average turbine blade radius = 5.62 inches or .468 feet.

Turbine blade speed = $2\pi r \times \frac{\text{r.p.m.}}{60} = .04901 \times \text{r.p.m.}$

Columns 54 and 55 show the calculation for turbine blade speed in feet per second.

Column 56 shows the value of the ratio of wheel speed to nozzle velocity.

Column 11 shows the relative loss Δp

Column 12 shows the relative loss Δp

Column 13 shows the relative loss Δp

$$\left(\frac{\partial p}{\partial x} \right) = \frac{\partial p}{\partial x}$$

$$\frac{\frac{\partial p}{\partial x}}{\frac{\partial p}{\partial x}} = 1$$

Column 14 shows the relative loss Δp

$$\frac{\partial p}{\partial x} = \frac{\partial p}{\partial x}$$

Column 15 shows the relative loss Δp

$$\frac{\partial p}{\partial x} = \frac{\partial p}{\partial x}$$

$$\frac{\partial p}{\partial x} = \frac{\partial p}{\partial x}$$

Column 16 shows the relative loss Δp

Column 17 shows the relative loss Δp

Column 18 shows the relative loss Δp

Column 19 shows the relative loss Δp

Column 20 shows the relative loss Δp

Column 21 shows the relative loss Δp

Column 22 shows the relative loss Δp

Column 57 shows turbine efficiencies as determined from column 56 and Figure 2.

Columns 58 through 62 show the calculation for turbine work in Btu/lb. of compressor air.

$$L_c = \int_{530}^{715.5} C_p dt - 44.6 \text{ Btu/lb. air}$$

An overall heat balance gives:

$$44.60 W_a + [L_T(W_a - W_b) - 44.6 W_a] = L_T(W_a - W_b)$$

or assuming $W_a = 1 \text{ lbs/sec.}$

$$(\text{Col. 62}) (W_b)^2 + [44.60 - 2 (\text{Col. 62})] W_b + \text{Col. 62} - 44.60 = 0$$

$$\text{let } a = \text{col. 62}$$

$$\text{let } b = 44.60 - 2 (\text{col. 62})$$

$$\text{let } c = \text{col. 62} - 44.60$$

$$\text{then } W_b = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

Columns 63 through 71 show the calculation for W_b in pounds of air per pound of compressor air.

Columns 72 through 95 show the calculation for C_p , k_g and L_T from information obtained from graphs of C_p for the various products of combustion for purposes of comparison with previously calculated results.

$$\text{Thermal efficiency} = \frac{\text{net heat output}}{\text{net heat input}} \times 100$$

$$= \frac{W_b \times W_a \times L_c \times 100}{19100}$$

$$19100$$

$$= \text{col. 71} \times \text{col. 4} \times .2335$$

Columns 96 and 97 show the calculations for thermal efficiency.

Let $f(x)$ be a function defined on the interval $[a, b]$.

Then the function $f(x)$ is said to be

continuous on $[a, b]$ if for every $\epsilon > 0$ there exists a $\delta > 0$ such that

whenever $|x - x_0| < \delta$ it follows that

$$|f(x) - f(x_0)| < \epsilon$$

where x_0 is any point in the interval $[a, b]$.

$$f(x) = \begin{cases} x^2 \sin \frac{1}{x} & x \neq 0 \\ 0 & x = 0 \end{cases}$$

is continuous at $x = 0$ because

$$|f(x) - f(0)| = |x^2 \sin \frac{1}{x} - 0| = x^2 |\sin \frac{1}{x}| \leq x^2$$

$$\text{and } x^2 < \epsilon \text{ whenever } |x| < \sqrt{\epsilon}$$

$$\text{for } 0 < \epsilon < 1$$

$$\text{hence } \lim_{x \rightarrow 0} f(x) = 0 = f(0)$$

Therefore $f(x)$ is continuous at $x = 0$.

Since $f(x)$ is continuous at every point of $[a, b]$,

it follows that $f(x)$ is continuous on $[a, b]$.

Let $f(x)$ be a function defined on the interval $[a, b]$.

Then the function $f(x)$ is said to be

uniformly continuous on $[a, b]$ if for every $\epsilon > 0$ there exists a $\delta > 0$ such that

$$|f(x) - f(y)| < \epsilon \text{ whenever } |x - y| < \delta$$

$$\text{for all } x, y \in [a, b]$$

where

$$|x - y| < \delta \text{ implies } |f(x) - f(y)| < \epsilon$$

where δ depends only on ϵ and not on x or y .

Appendix A

Tables of Calculations assuming a compressor pressure ratio of 2.00 and a burner temperature of 1960°R at point 2 on figure 1. $18500\text{ RPM} = 907\text{ ft/sec.}$

Temperature rise factor = .31

$$T_{02} = 530 + .31 (530) = 694^{\circ}\text{R}$$

Using Hecks Gas Tables

$$18427 - x(1763.5) = W_a (328.0)$$

Columns A1 through A4 show the calculation for the pounds of air per pound of fuel.

Columns A5 through A11 show the calculations for L_T using the applicable figures from Appendix 1.

$$L_c = \int_{530}^{694} C_p dT = 39.38 \text{ Btu/lb. of air.}$$

In the same manner as in Appendix 1, an overall heat balance gives

$$(\text{Col. A11})(W_b)^2 + [39.38 - 2(\text{Col. A11})]W_b + \text{Col. A11} - 39.38 = 0$$

$$\text{let } a = \text{Col. A11} \quad \text{let } b = 39.38 - 2(\text{Col. A11})$$

$$\text{let } c = \text{Col. A11} - 39.38$$

and solve for W_b

Columns A12 through A20 show the calculations for W_b

Column A21 shows the calculation for thermal efficiency.

$$\text{Thermal efficiency} = W_a \times W_b \times \frac{39.38 \times 100}{19100}$$

$$= W_a \times W_b \times .206$$

Let $f(x)$ be a function defined on $[a, b]$. Then the definite integral of $f(x)$ from a to b is denoted by $\int_a^b f(x) dx$.

$$\int_a^b f(x) dx = F(b) - F(a)$$

where $F(x)$ is an antiderivative of $f(x)$. The definite integral represents the net area under the curve $y = f(x)$ from $x = a$ to $x = b$.

For example, if $f(x) = x^2$, then $\int_0^1 x^2 dx = \frac{1}{3}$.

$$\int_0^1 x^2 dx = \left[\frac{x^3}{3} \right]_0^1 = \frac{1}{3}$$

is the area under the curve $y = x^2$ from $x = 0$ to $x = 1$.

$$\int_a^b f(x) dx = \lim_{n \rightarrow \infty} \sum_{i=1}^n f(x_i^*) \Delta x$$

$$\Delta x = \frac{b-a}{n}$$

$$x_i^* = a + (i-1)\Delta x$$

$$i = 1, 2, \dots, n$$

where Δx is the width of each subinterval.

The definite integral is a linear operator.

$$\int_a^b (cf(x) + dg(x)) dx = c \int_a^b f(x) dx + d \int_a^b g(x) dx$$

$$\int_a^b f(x) dx = - \int_b^a f(x) dx$$

Appendix B

Tables of calculations assuming a compressor pressure ratio of 1.80 and a burner temperature of 1960°R at point 3 on Figure 1. 17000 RPM = 834 ft/sec.

Temperature rise factor = .25

$$T_{02} = 530 + .25 (530) = 662.4^{\circ}\text{R}$$

Using Hecks Gas Tables

$$18120.3 - x(1763.5) = W_a(335.6)$$

Columns B1 through B4 show the calculations for the pounds of air per pound of fuel.

$$M_5 = \sqrt{\frac{2}{k-1} \left[\left(\frac{P_{05}}{P_{06}} \right)^{\frac{k-1}{k}} - 1 \right]}$$

$$\text{and } v_n = \frac{M_5 \sqrt{k g R_g T_{05}}}{\sqrt{1 + \frac{k-1}{2} M_5^2}}$$

Since $\frac{P_{05}}{P_{06}}$ is less than the critical pressure ratio for the gases of combustion, v_n must be calculated from the Mach. number in the nozzle throat. Columns B5 through B14 show these calculations, using applicable figures from Appendix 1.

Columns B15 through B21 show the calculations for turbine work in Btu per pound of compressor air.

$$L_c = \int_{530}^{662.4} C_p dT = 31.87 \text{ Btu/lb. air.}$$

APPENDIX

TABLE OF INTEGRALS OF FUNCTIONS OF THE FORM

$y = ax^2 + bx + c$ OR $y = a/x^2 + b/x + c$ OR $y = a/x^2 + b/x + c$ OR $y = a/x^2 + b/x + c$

THESE INTEGRALS ARE GIVEN IN THE FOLLOWING TABLE

$$\int \frac{1}{x^2 + a^2} dx = \frac{1}{a} \tan^{-1} \frac{x}{a} + C$$

THESE INTEGRALS ARE GIVEN IN THE FOLLOWING TABLE

$$\int \frac{1}{x^2 - a^2} dx = \frac{1}{2a} \ln \left| \frac{x-a}{x+a} \right| + C$$

THESE INTEGRALS ARE GIVEN IN THE FOLLOWING TABLE

THESE INTEGRALS ARE GIVEN IN THE FOLLOWING TABLE

$$\int \frac{1}{x^2 + a^2} dx = \frac{1}{a} \tan^{-1} \frac{x}{a} + C$$

$$\int \frac{1}{x^2 - a^2} dx = \frac{1}{2a} \ln \left| \frac{x-a}{x+a} \right| + C$$

THESE INTEGRALS ARE GIVEN IN THE FOLLOWING TABLE

THESE INTEGRALS ARE GIVEN IN THE FOLLOWING TABLE

THESE INTEGRALS ARE GIVEN IN THE FOLLOWING TABLE

THESE INTEGRALS ARE GIVEN IN THE FOLLOWING TABLE

THESE INTEGRALS ARE GIVEN IN THE FOLLOWING TABLE

THESE INTEGRALS ARE GIVEN IN THE FOLLOWING TABLE

THESE INTEGRALS ARE GIVEN IN THE FOLLOWING TABLE

$$\int \frac{1}{x^2 + a^2} dx = \frac{1}{a} \tan^{-1} \frac{x}{a} + C$$

Setting up a heat balance in the same manner
as in appendix 1

$$(\text{Col. B21})(W_b)^2 + [31.87 - 2(\text{Col. B21})] W_b + \text{Col. B21} - 31.87 = 0$$

$$\text{let } a = \text{Col. B 21} \quad \text{let } b = 31.87 - 2(\text{Col. B 21})$$

$$\text{let } c = \text{Col. B 21} - 31.87$$

and solve for W_b

Columns B22 through B30 show the calculations for W_b

$$n = W_a \times W_b \times \frac{39.38 \times 100}{19100}$$

$$\text{or} \quad n = W_a \times W_b \times .167$$

Column B31 shows the thermal efficiency.

12

Appendix C

Table of calculations assuming a compressor pressure ratio of 2.20 and a burner temperature of 1860°R at point 1 on Figure 1. 19660 RPM = 963 ft./sec.

Temperature rise factor = .35

$$T_{02} = 530 + .35(530) = 715.5 \text{ R}$$

Using Hecks Gas Tables

$$18237.7 - 1608.3 x = W_a(295.2)$$

Columns C1 through C10 show the calculations for the weight of air per pound of fuel and the weight of the total combustion products per pound of fuel.

Columns C11 through C16 show the calculations for R_g .

Columns C17 through C26 show the calculations for C_p and k_g using information obtained from the graphs of C_p for the products of combustion and the formula.

$$C_p = \frac{k}{k-1} \frac{R}{J}$$

$$\text{or } k = \frac{\frac{J}{R} C_p}{\frac{J}{R} C_p - 1}$$

Columns C27 through C33 show the calculations for nozzle throat velocity and turbine efficiency.

Columns C34 through C41 show the calculations for turbine work.

In the same manner as in Appendix I, an overall heat balance gives:

This is a preliminary report on the results of the first part of the investigation. The results of the second part will be published in a separate paper. The results of the third part will be published in a separate paper. The results of the fourth part will be published in a separate paper. The results of the fifth part will be published in a separate paper. The results of the sixth part will be published in a separate paper. The results of the seventh part will be published in a separate paper. The results of the eighth part will be published in a separate paper. The results of the ninth part will be published in a separate paper. The results of the tenth part will be published in a separate paper.

The results of the first part of the investigation are as follows: The results of the second part of the investigation are as follows: The results of the third part of the investigation are as follows: The results of the fourth part of the investigation are as follows: The results of the fifth part of the investigation are as follows: The results of the sixth part of the investigation are as follows: The results of the seventh part of the investigation are as follows: The results of the eighth part of the investigation are as follows: The results of the ninth part of the investigation are as follows: The results of the tenth part of the investigation are as follows:

$$\begin{aligned}
 & \frac{1}{2} \left(\frac{1}{2} \right) = \frac{1}{4} \\
 & \frac{1}{2} \left(\frac{1}{2} \right) = \frac{1}{4} \\
 & \frac{1}{2} \left(\frac{1}{2} \right) = \frac{1}{4}
 \end{aligned}$$

The results of the first part of the investigation are as follows: The results of the second part of the investigation are as follows: The results of the third part of the investigation are as follows: The results of the fourth part of the investigation are as follows: The results of the fifth part of the investigation are as follows: The results of the sixth part of the investigation are as follows: The results of the seventh part of the investigation are as follows: The results of the eighth part of the investigation are as follows: The results of the ninth part of the investigation are as follows: The results of the tenth part of the investigation are as follows:

$$(\text{Col. C41})(W_b)^2 + [44.60 - 2(\text{Col. C41})]W_b + \text{Col. C41} - 44.60 = 0$$

$$\text{let } a = \text{Col. C41} \qquad \text{let } b = 44.60 - 2(\text{Col. C41})$$

$$\text{let } c = \text{Col. C41} - 44.60$$

and solve for W_b

Columns C42 through C50 show the calculations for W_b in pounds of air per pound of compressor air.

In the same manner as in Appendix I

$$n = W_a \times W_b \times .2335$$

Columns 51 and 52 show the calculation for thermal efficiency.

Appendix D

Table of calculations assuming a compressor pressure ratio of 2.20 and a burner temperature of 1760°R at point 1 on Figure 1. 19660 RPM = 953 ft/sec.

Temperature rise factor = .35

$$T_{o2} = 530 + .35(530) = 715.5^{\circ}\text{R}$$

Using Hecks Gas Tables

$$18316.5 - 1553.6x = 268.8W_a$$

Columns D1 through D10 show the calculations for the weight of air per pound of fuel and the weight of the total combustion products per pound of fuel.

Columns D11 through D16 show the calculations for R_g .

Columns D17 through D26 show the calculations for C_p and k_g using information obtained from the graphs of C_p for the products of combustion and the formula

$$C_p = \frac{k}{k-1} \frac{R}{J}$$

$$\text{or } k = \frac{\frac{J}{R} C_p}{\frac{J}{R} C_p - 1}$$

Columns D27 through D33 show the calculations for nozzle throat velocity and turbine efficiency.

Columns D34 through D41 show the calculations for turbine work.

In the same manner as in Appendix I an overall heat balance gives:

CHAPTER I

THE first object of this chapter is to show that the function $f(x)$ is continuous at $x = a$ if and only if $\lim_{x \rightarrow a} f(x) = f(a)$. This is the definition of continuity at a point.

Let $f(x)$ be a function defined on the interval (a, b) .

Let x_0 be a point in the interval (a, b) .

Let $\epsilon > 0$ be a positive number.

Let $\delta > 0$ be a positive number.

Suppose that for every $\epsilon > 0$ there exists a $\delta > 0$ such that if $|x - x_0| < \delta$ then $|f(x) - f(x_0)| < \epsilon$. Then $f(x)$ is continuous at x_0 .

Suppose that for every $\epsilon > 0$ there exists a $\delta > 0$ such that if $|x - x_0| < \delta$ then $|f(x) - f(x_0)| < \epsilon$. Then $f(x)$ is continuous at x_0 .

$$\lim_{x \rightarrow a} f(x) = f(a)$$

$$\lim_{x \rightarrow a} \frac{f(x)}{g(x)} = \frac{\lim_{x \rightarrow a} f(x)}{\lim_{x \rightarrow a} g(x)}$$

Suppose that $f(x)$ and $g(x)$ are functions defined on the interval (a, b) . Suppose that $\lim_{x \rightarrow a} f(x) = L$ and $\lim_{x \rightarrow a} g(x) = M$. Then $\lim_{x \rightarrow a} \frac{f(x)}{g(x)} = \frac{L}{M}$ if $M \neq 0$.

THEOREM

If $f(x)$ is continuous at $x = a$ and $g(x)$ is continuous at $x = a$, then $f(x)g(x)$ is continuous at $x = a$.

(THEOREM 1.1)

$$(\text{Col. D41})(w_b)^2 + [44.60 - 2(\text{Col. D41})]w_b + \text{Col. D41} - 44.60 = 0$$

$$\text{let } a = \text{Col. D41} \quad \text{let } b = 44.60 - 2(\text{Col. D41})$$

$$\text{let } c = \text{Col. D41} - 44.60$$

and solve for w_b

Columns D42 through D50 show the calculation for w_b in pounds of air per pound of compressor air.

In the same manner as in appendix 1

$$n = w_a \times w_b \times .2335$$

Columns E51 and E52 show the calculation for thermal efficiency.

1. The first part of the paper is devoted to a study of the

properties of the function $f(x)$ defined by the equation

$$f(x) = \frac{1}{2} (f(x-1) + f(x+1))$$

for $x \in [0, 1]$.

It is shown that the function $f(x)$ is continuous on the interval

$[0, 1]$ and that it satisfies the functional equation

$$f(x) = \frac{1}{2} (f(x-1) + f(x+1))$$

for $x \in [0, 1]$.

It is also shown that the function $f(x)$ is unique in the class of

continuous functions satisfying the functional equation

$f(x) = \frac{1}{2} (f(x-1) + f(x+1))$ for $x \in [0, 1]$.

The second part of the paper is devoted to a study of the

properties of the function $g(x)$ defined by the equation

$$g(x) = \frac{1}{2} (g(x-1) + g(x+1))$$

for $x \in [0, 1]$.

It is shown that the function $g(x)$ is continuous on the interval

$[0, 1]$ and that it satisfies the functional equation

$$g(x) = \frac{1}{2} (g(x-1) + g(x+1))$$

for $x \in [0, 1]$.

It is also shown that the function $g(x)$ is unique in the class of

continuous functions satisfying the functional equation

$g(x) = \frac{1}{2} (g(x-1) + g(x+1))$ for $x \in [0, 1]$.

The third part of the paper is devoted to a study of the

properties of the function $h(x)$ defined by the equation

$$h(x) = \frac{1}{2} (h(x-1) + h(x+1))$$

for $x \in [0, 1]$.

It is shown that the function $h(x)$ is continuous on the interval

Appendix E

Tables of calculations assuming a compressor pressure ratio of 2.20 and a burner temperature of 1660°R at point 1 on Figure 1. 19660 RPM = 963 ft/sec.

$$\text{Temperature rise factor} = .35$$

$$T_{02} = 530 + .35(530) = 715.5^{\circ}\text{R.}$$

Using Hecks Gas Tables

$$18394.2 - 1499.7x = 240.8 W_a$$

Columns E1 through E10 show the calculations for the weight of air per pound of fuel and the weight of the total combustion products per pound of fuel.

Columns E11 through E16 show the calculations for R_g .

Columns E17 through E26 show the calculations for C_p and k_g using information obtained from the graphs of C_p for the products of combustion and the formula

$$C_p = \frac{k}{k-1} \frac{R}{J}$$

$$\text{or } k = \frac{\frac{J}{R} C_p}{\frac{J}{R} C_p - 1}$$

Columns E27 through E33 show the calculations for nozzle throat velocity and turbine efficiency.

Columns E34 through E41 show the calculations for turbine work.

In the same manner as in Appendix 1 an overall heat balance gives:

$$(\text{Col. E41})(W_b)^2 + [44.60 - 2(\text{Col. E41})]W_b + \text{Col. E41} - 44.60 = 0$$

$$\text{let } a = \text{Col. E41} \quad \text{let } b = 44.60 - 2(\text{Col. E41})$$

$$\text{let } c = \text{Col. E41} - 44.60$$

and solve for W_b

Columns E42 through E50 show the calculations for W_b in pounds of air per pound of compressor air.

In the same manner as in Appendix 1

$$n = W_a \times W_b \times .2335$$

Columns D51 and D52 show the calculations for thermal efficiency.
